EnsEMBL COMPARA PERL API TUTORIAL

By Cara Woodwark and Abel Ureta-Vidal

Revisions: CW Jun 04, AUV Aug 04.

WARNING: this is still a first draft. A polished version of it in sync with ensembl release 24 (in

September 2004) should be available at the time of release. By now this tutorial should work

with the cvs main trunk of the code (so don't specify -r branch-ensembl-24), and with ensembl

databases release 23 (at least for whole genome alignment part, as some changes have

been done to the tables that hold the orthologues data).

Introduction

This tutorial is an introduction to the ensembl compara API. A knowledge of the

ensembl core API is presumed, it is assumed that concepts and conventions presented in the

ensembl core API tutorial have been assimilated by the user. The ensembl core API tutorial

can be found at http://www.ensembl.org/???? (in cvs.

ensembl/docs/tutorial/ensembl_tutorial.pdf) and should be read first as it provides a

comprehensive guide to the ensembl environment.

compara database A documentation schema is available about the

http://www.ensembl.org/???? (in cvs ensembl-compara/docs/docs/schema_doc.html), and

while not necessary for this tutorial, an understanding of the database tables may help, as

many of the Adaptor modules are table specific.

Obtaining the code

To use the ensembl compara API, you have the same requirement that when using

the ensembl core API i.e. perl 5.6 or later, bioperl 1.2 or later, DBI, DBD::mysql and ensembl

core code. Please refer to the ensembl core API tutorial that will tell you everything about

these modules, how and where to get them.

In addition, you will need the ensembl compara code that is available by cvs from the

ensembl cvs repository using the following cvs commands:

cvs -d :pserver:cvsuser@cvsro.sanger.ac.uk:/cvsroot/CVSmaster login

When prompted the password is 'CVS'.

```
cvs -d :pserver:cvsuser@cvsro.sanger.ac.uk:/cvsroot/CVSmaster co -r branch-ensembl-24 ensembl-compara
```

This will check out ensembl-compara code for stable branch 24. Make sure the ensembl core code you have already checked out is on the same branch. Note that the branch that is checked out should correspond to the database version being used. Thus ensembl_compara_24_1 and e.g. homo-sapiens_core_24_34e and mus_musculus_core_24_33 should be used with the above ensembl branch 24 code.

Environment Variables

The following PERL5LIB environment variables should be set up:

```
under tcsh/csh shell with
setenv PERL5LIB ${PERL5LIB}:{HOME}/src/bioperl-live: \
${HOME}/src/ensembl/modules:${HOME}/src/ensembl-compara/modules
under bash shell with
export PERL5LIB=${PERL5LIB}:{HOME}/src/bioperl-live: \
${HOME}/src/ensembl/modules:${HOME}/src/ensembl-compara/modules
```

These presume that bioperl and ensembl are in a directory called src set up in your home directory.

Code Conventions (and unconventions)

Refer to the ensembl core tutorial for a good description of the coding conventions normally used in ensembl. Due to historical accidents, there may be exceptions to these rules in compara, especially with respect to variable names.

Connecting a ensembl compara database

Explicitely, using the Bio::EnsEMBL::Compara::DBSQL::DBAdaptor

Ensembl compara data as ensembl core data, is stored in a MySQL relational database. If you want to access a compara database, you will need to connect to it. This is done in exactly the same way as when connecting an ensembl core database, but using a Compara specific DBAdaptor.

As for a ensembl core connection, in addition to the parameters provided above, the optional port, driver and pass parameters can also be used to specify the TCP connection port, the type of database driver and the password respectively. These values have sensible defaults and can often be omitted.

Implicitely, using the Bio::EnsEMBL::Registry (recommended)

To use the registry you will need to have a registry configuration file set up. An example of such file can be found in ensembl/modules/Bio/EnsEMBL/Utils/ensembl_init.example, and below you have a slightly modified copy of it.

```
# Example of configuration file used by Bio::EnsEMBL::Registry::load_all method
# to store/register all kind of Adaptors.
use strict;
use Bio::EnsEMBL::Utils::ConfigRegistry;
use Bio::EnsEMBL::DBSOL::DBAdaptor:
use Bio::EnsEMBL::Compara::DBSQL::DBAdaptor;
my @aliases;
new Bio::EnsEMBL::DBSQL::DBAdaptor(-host => 'ensembldb.ensembl.org',
                                   -user => 'anonymous',
                                   -port => 3306,
                                   -disconnect_when_inactive => 1,
-species => 'Homo sapiens',
                                   -group => 'core',
                                   -dbname => 'homo sapiens core 23 34e');
@aliases = ('H_Sapiens', 'homo sapiens', 'Homo_Sapiens', 'Homo_sapiens', 'Homo',
'homo', 'human');
Bio::EnsEMBL::Utils::ConfigRegistry->add_alias(-species => "Homo sapiens",
                                                -alias => \@aliases);
new Bio::EnsEMBL::DBSQL::DBAdaptor(-host => 'ensembldb.ensembl.org',
                                    -user => 'anonymous',
                                   -port => 3306,
                                   -disconnect_when_inactive => 1,
                                   -species => 'Mus musculus',
                                   -group => 'core',
                                   -dbname => 'mus_musculus_core_23_32c');
@aliases = ('M_Musculus', 'mus musculus', 'Mus_Musculus', 'Mus_musculus', 'Mus', 'mus',
Bio::EnsEMBL::Utils::ConfigRegistry->add_alias(-species => "Mus musculus",
                                                -alias => \@aliases);
-port => 3306,
                                   -disconnect_when_inactive => 1,
-species => 'Fugu rubripes',
                                   -group => 'core'
                                   -dbname => 'fugu_rubripes_core_23_2c');
@aliases = ('F_Rubripes', 'fugu rubripes', 'Fugu_Rubripes', 'Fugu_rubripes', 'Fugu',
'fugu');
Bio::EnsEMBL::Utils::ConfigRegistry->add_alias(-species => "Fugu rubripes",
                                                -alias => \@aliases);
new Bio::EnsEMBL::Compara::DBSQL::DBAdaptor(-host => 'ensembldb.ensembl.org',
```

```
-user => 'anonymous',
-port => 3306,
-disconnect_when_inactive => 0,
-species => 'Compara23',
-dbname => 'ensembl_compara_23_1');

@aliases = ('ensembl_compara_23_1', 'compara23');

Bio::EnsEMBL::Utils::ConfigRegistry->add_alias(-species => "Compara23",
-alias => \@aliases);

1;
```

In this configuration file, you can list all the parameters needed to connect a compara database. The compara database is a multi-species database that contains comparative genomic information on all ensembl species. One should then be able not only to connect to a compara database but also to every species ensembl core database. The use of the registry configuration file lets you the freedom to list connection parameters for all ensembl core databases you might need to access in relation to ensembl compara data (in our example, only 3 are mentioned, human, mouse and rat). All this information is then in a single central place, easy to maintain (modify or update).

The access to database adaptor is done using either the species alias (specified by the - species parameter) or one of the aliases specified (in the @aliases array). No need to remember the complete database name, an alias is enough.

The parameter disconnect_when_active set to 1 for all ensembl core databases. The main purpose of this is that many time when accessing compara data, you won't need to access any of the core databases. There is no need then to keep open connections to unused databases. The disconnect_when_active set to 1, automatically disconnect from databases when no use of the connection is done, and will reconnect automatically when needed. This helps to reduce connection load to the MySQL server used.

Alias.

Ensembl compara Adaptors available

```
GenomeDBAdaptor
                              to fetch Bio::EnsEMBL::Compara::GenomeDB Objects
                             to fetch Bio::EnsEMBL::Compara::DnaFrag Objects
DnaFragAdaptor
                             to fetch Bio::EnsEMBL::Compara::GenomicAlign Objects
GenomicAlignAdaptor
DnaAlignFeatureAdaptor
                             to fetch Bio::EnsEMBL::DnaDnaAlignFeature Objects (note
that this adaptor return a ensembl core object)
SyntenyAdaptor
                             to fetch Bio::EnsEMBL::Compara::SyntenyRegion Objects
                             to fetch Bio::EnsEMBL::Compara::Member Objects
MemberAdaptor
TaxonAdaptor
                             to fetch Bio::EnsEMBL::Compara::Taxon Objects
                             to fetch Bio::EnsEMBL::Compara::Homology Objects
HomologyAdaptor
FamilyAdaptor
                             to fetch Bio::EnsEMBL::Compara::Family Objects
                                   fetch
                                            Bio::EnsEMBL::Compara::PeptideAlignFeature
PeptideAlignFeatureAdaptor
objects
                             to query the meta table
MetaContainer
```

Only some of these adaptors will be used for illustration as part of this tutorial through commented perl scripts code.

Whole Genome Alignments

The compara database contains a number of different types of whole genome alignments. A much detailed information about what are these different types can be found here

```
http://www.ensembl.org/Homo_sapiens/helpview?se=1&kw=contigview#mus_musculus_match
```

The full range of comparisons available may be found in the method_link table as shown below.

The designation 'TIGHT' denotes that the alignments have been rescored using the 'TIGHT' matrix (in cvs, ensembl-compara/scripts/hcr/tight.mat) so only the most highly conserved alignments are reported.

The whole genome comparisons are accessed through the API by way of the adaptors mentioned above. Specifically, the DnaAlignFeatureAdaptor, which returns DnaAlignFeatures (illustrated in this tutorial) and the GenomicAlignAdaptor, which allows direct access to all of the data in the genomic_align_block table (not illustrated in this tutorial for now).

DnaDnaAlignFeature objects (for pairwise alignments only)

Below it is a commented perl script which a simplified version of the ensembl-compara/scripts/dumps/DumpAlignments.pl script that you can get from the ensembl-compara cvs repository.

```
--seg region end integer
                                  (e.g. 50500000)
                                  (e.g. human) the query species (i.e. a
   --qy string
                                 Bio::EnsEMBL::Registry alias) from which alignments
                                  are queried and seq_region refer to
   --tg string
                                  (e.g. mouse) the target sepcies (i.e. a
                                  Bio::EnsEMBL::Registry alias) to which alignments are
                                 queried
  [--alignment type string]
                                  (e.g. TRANSLATED BLAT) type of alignment stored
                                  (default: BLASTZ_NET)
  [--tsl]
                                  print out a translated alignment
  [--00]
                                 Original orientation output from the alignment
                                 program. Mostly useful in association with -tsl
                                 option, when a full translated alignment program has
                                 been used e.g TRANSLATED_BLAT (helps to obtain the
                                 right translation phaseused during the alignment
                                 process)
  [--ft string]
                                 alignment format, available in bioperl Bio::AlignIO
                                  (default: clustalw)
  [--uc]
                                 print out sequence in upper cases (default is lower
                                 cases)
                                 (e.g. \overset{'}{2}) limit the output to the number of alignments specified
  [--limit integer]
  [--reg conf filepath]
                                 the Bio::EnsEMBL::Registry configuration file. If none
                                  given, the one set in ENSEMBL_REGISTRY will be used if
                                 defined, if not ~/.ensembl_init will be used.

```

Now on the same region, TRANSLATED_BLAT alignments against fugu in clustalw format, but at translation level now (-tsl) not nucleaotide level, we can run the following command line,

To make sure that the alignment, we got is on the strand on which it was originally generated using the -oo option will check that and restore the right strandness. See below the difference in the translation level alignment obtained.

SyntenyRegion objects

NB: This part needs an update. Some part of it may be out of date soon....

The DNA/DNA whole genome comparisons are also used to create long regions of synteny between chromosomes of different species. For example, the ENCODE region on chromosome 22 used previously is syntenous to regions on chromosomes 10, 5 and 11 of mouse. This information is available through the SyntenyAdaptor. The following script returns the mouse regions that are syntenous with this ENCODE region.

```
use Bio::EnsEMBL::Compara::DBSQL::DBAdaptor;
use Bio::EnsEMBL::Transcript;
mv Shost = 'ensembldb.ensembl.org';
my $user = 'anonymous';
my $dbname = 'ensembl_compara_22_1';

```

Orthologues and Protein clusters

NB: This following is very much a draft at this stage with some piece of code to give examples, but not much comments. Will be added by September 2004.

Member objects (for pairwise alignments only)

```
my $ma = Bio::EnsEMBL::Registry->get adaptor($dbname,'compara','Member');
my $member = $ma->fetch_by_source_stable_id("ENSEMBLGENE",ENSP0000000233);
print join " ", map { $member->$_ } qw(chr_name chr_start chr_end description
source_name taxon_id taxon),"\n";
chr name, chr start, chr end and description are self-explanatory.
source_name tells about the origin of the Member entry, and can be either
        ENSEMBLPEP, derived from ensembl translation,
        or ENSEMBLGENE, derived from an ensembl gene,
        or SWISSPROT, derived from a swissprot entry,
        or SPTREMBL, derived from a sptrembl entry.
taxon_id e.g. 9606 correspond to the NCBI taxonomy identifier (see www.ncbi.nih.gov for
more details).
taxon returns a Bio::EnsEMBL::Compara::Taxon object that inherits itself from Bio::Species, so
from this object you can get
my = \mbox{my staxon} = \mbox{member->taxon}; print join "; ", map { \mbox{staxon->}\mbox{}_{-} } qw(common_name genus species binomial classification),"\n";
respectively for these method call and in the case of human species, you will obtain
human; Homo; sapiens; Homo sapiens; sapiens Homo Hominidae Catarrhini Primates
Eutheria Mammalia Euteleostomi Vertebrata Craniata Chordata Metazoa Eukaryota
Homology objects
# first you have to get a Member object. In case of homology is a gene, in
# case of family it can be a gene or a protein
my $ma = Bio::EnsEMBL::Registry->qet adaptor($dbname,'compara','Member');
my $member = $ma->fetch_by_source_stable_id("ENSEMBLGENE",ENSP0000000233);
# then you get the homologies where the member is implicated
my $ha = Bio::EnsEMBL::Registry->get adaptor($dbname,'compara','Homology');
my $homologies = $ha->fetch_by_Member($member);
fetch_by_Member_Homology_source (fetch_by_Member_MethodLink)
# Then for each homology, you get all the Members implicated
foreach my homology (@{homologies}) {
 print $homology->description
# each homology relation have only 2 members, you should find there
# the initial member used in the first fetching
for each my $member_attribute (@{$homology->get_all_Member_Attribute})
# for each Member, you get information on the Member specifically or in
# relation to the homology relation via Attribute object
    my ($member, $attribute) = @{$member_attribute};
print join " ", map { $member->$_ } qw(stable_id taxon_id),"\n";
print join " ", map { $attribute->$_ } qw(perc_id perc_pos perc_cov),"\n";
  }
```

```
# You can even retrieve the HSP alignment between the 2 proteins,
# HSP used to build the homology releationship at the peptide level
  my $sa = $homology->get_SimpleAlign();
 my $alignIO = Bio::AlignIO->newFh(-interleaved => 0,
                                   -fh => \*STDOUT,
                                   -format => "clustalw",
                                   -idlength => 20);
  print $alignIO $sa;
# or at the nucleotide level. You will need to make you have a connection to
# the corresponding core databases through the Bio::EnsEMBL::Registry
  $sa = $homology->get_SimpleAlign("cdna");
  my $alignIO = Bio::AlignIO->newFh(-interleaved => 0,
                                   -fh => \*STDOUT,
                                   -format => "phylip",
                                   -idlength => 20);
  print $alignIO $sa;
Family objects
my $ma = Bio::EnsEMBL::Registry->get_adaptor($dbname,'compara','Member');
my $member = $ma->fetch_by_source_stable_id("ENSEMBLGENE", ENSP00000000233);
my $fa = Bio::EnsEMBL::Registry->get_adaptor($dbname,'compara','Family');
my $families = $fa->fetch by Member($member);
foreach my $family (@{$families}) {
print $family->description;
```

-fh => *STDOUT,
-format => "phylip",
-idlength => 20);

-fh => *STDOUT,
-format => "phylip",
-idlength => 20);

for each my \$member_attribute (@{\$family->get_all_Member_Attribute})

my (\$member, \$attribute) = @{{\$member_attribute};
print \$member->stable_id," ",\$member->taxon_id,"\n";

my \$alignIO = Bio::AlignIO->newFh(-interleaved => 0,

my \$alignIO = Bio::AlignIO->newFh(-interleaved => 0,

print \$attribute->cigar_line,"\n";

my \$sa = \$family->get_SimpleAlign();

\$sa = \$family->get_SimpleAlign("cdna");

print \$alignIO \$sa;

print \$alignIO \$sa;
